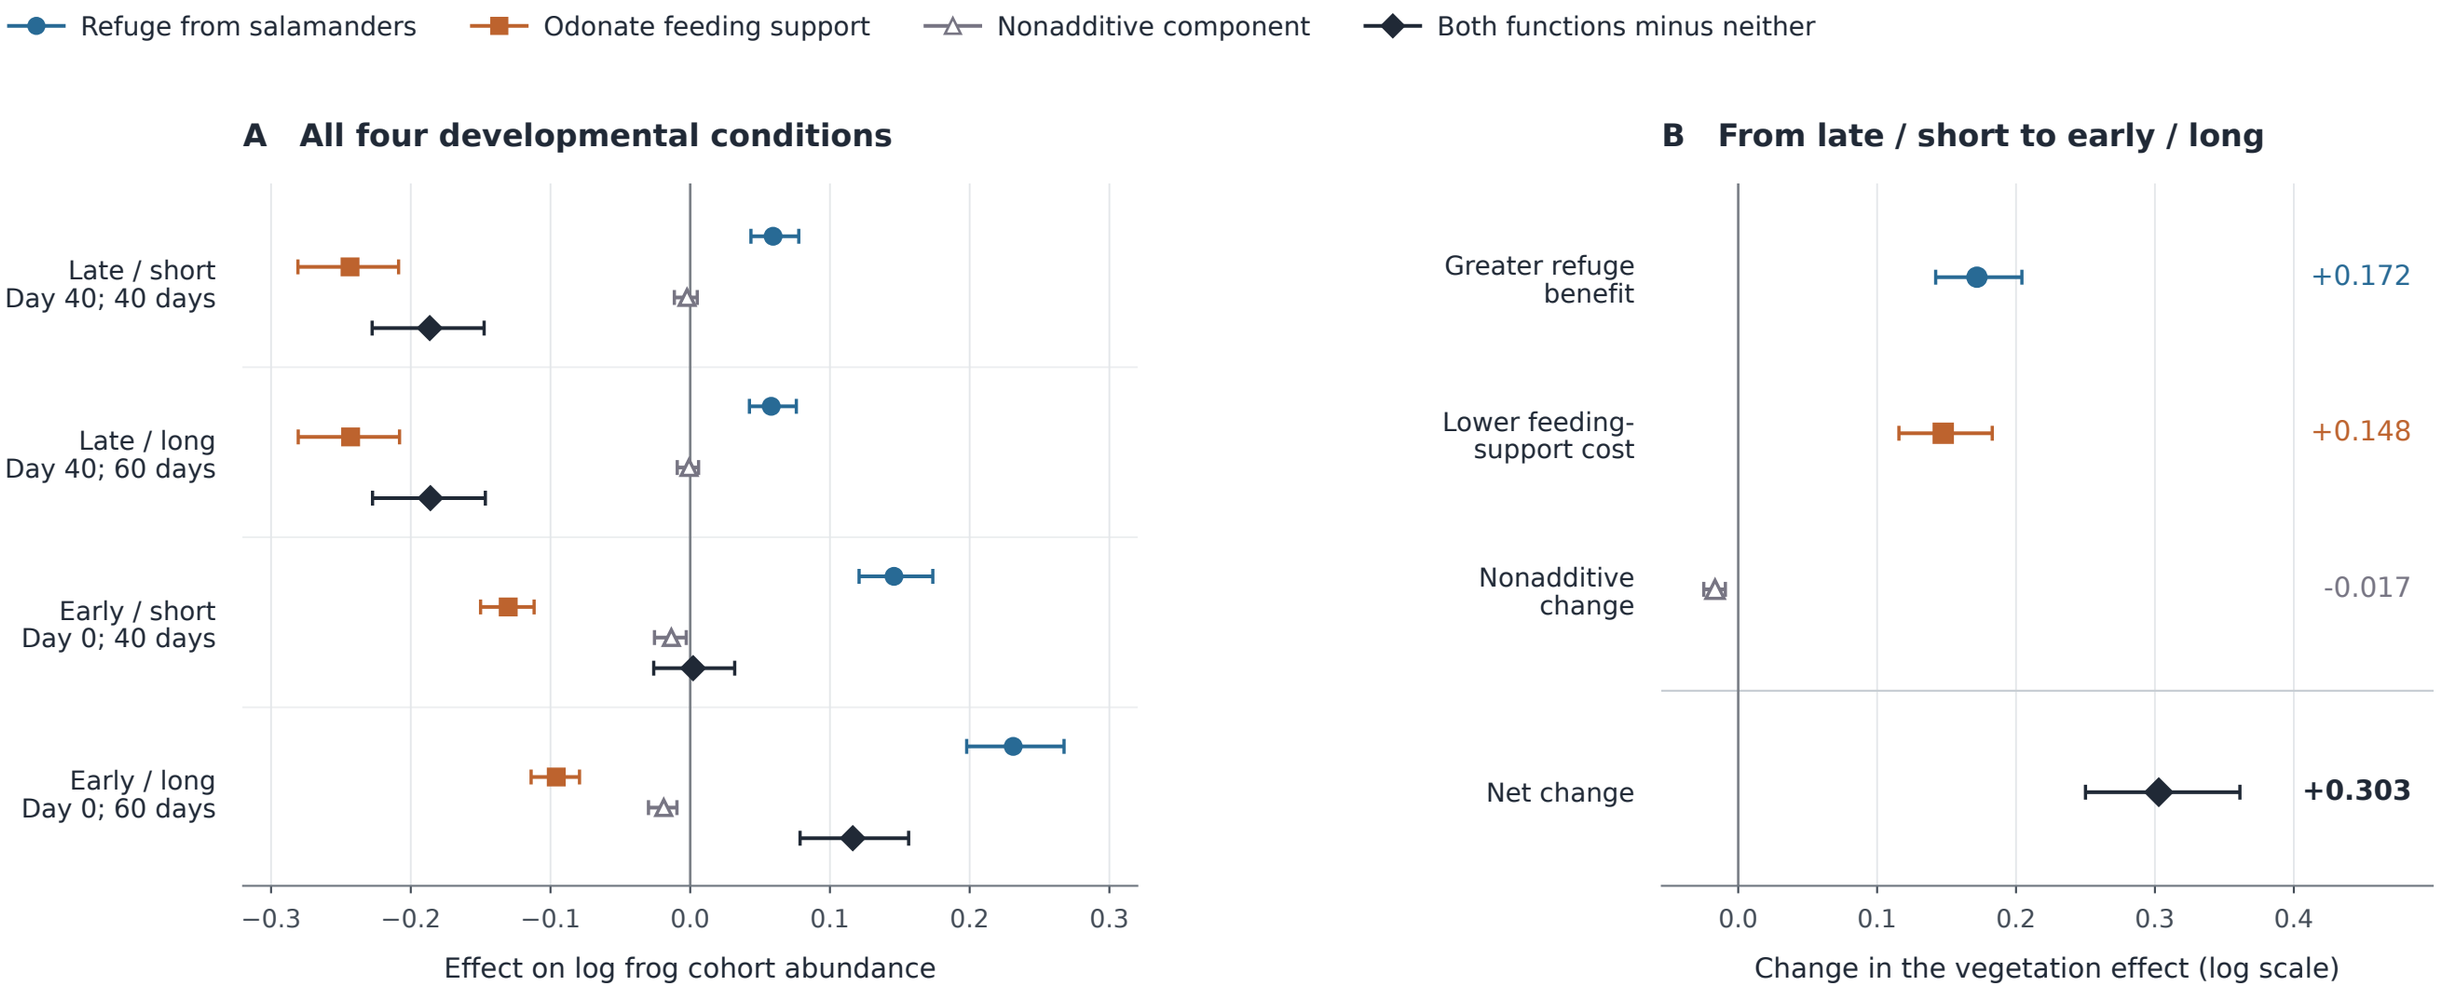
Why the vegetation effect changes sign

P1 model experiment | Salamander arrival and aquatic duration, with two vegetation functions crossed



Post hoc decomposition of the complete model factorial: 256 matched food-web backgrounds; all four function arms retained.

Points show means; intervals are pointwise 95% paired source-bootstrap ranges (10,000 resamples). Components sum to the net effect.

Both-minus-neither switches only the two focal functions. Values describe simulated aquatic frog cohorts, not measured field responses.
